Often referred to as the "missing link" in control systems because it was missing in the early motors that could be controlled by a computer, the 1313 can be viewed as the equivalent of the low-end control units in today's cars. The manual states that the motor/tachometer input is "not isolated" but has a high impedance, meaning it may be required for certain motor applications and if connected to a tachometer, it can be used with low-voltage sensors. The manual also states that the motor has a DC peak voltage of 20.0 V and can handle up to 21.2 V. The manual provides lists of all the various outputs of the 1313. References External links Category:Mechanical controlsMixed connective tissue disease: factors influencing the prognosis. The prognosis of mixed connective tissue disease (MCTD) has been reported to be poor. However, few studies have reported factors influencing prognosis. To clarify the prognosis of MCTD, we examined the clinical course of MCTD with a specific focus on the prognostic factors. Twenty-four patients with MCTD were included in this study. The prognostic factors were evaluated by a multiple regression analysis. The mean duration of follow-up was 3.1 years (range 1-16.3). At the last visit, 18 patients (75%) had completely recovered, and the remaining 6 patients (25%) still had active disease. The 6-year survival rate was 89% (CI = 77-97%). Multiple regression analysis showed that arterial hypertension and clinical activity were prognostic factors for poor prognosis. However, these prognostic factors were significant only in the first 2 years of the observation period. The patients were classified into a mild/moderate group and a severe group on the basis of initial level of C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR). The initial level of ESR was the only significant prognostic factor for the severe group. The period of follow-up was significantly shorter for the severe group (p Paraná de Minas Paraná de Minas 82157476af
